DEER 2004  
Session 1 – Emerging Diesel Technology  
Diesel Aftertreatment

Once it has “emerged”...

**...NO<sub>x</sub> aftertreatment has the potential to improve diesel engine fuel economy over current state-of-the-art**

# Table of Contents

## **Chapter 1: NO<sub>x</sub> adsorbers fuel penalty**

NO<sub>x</sub> chemistry

HC slip

Oxygen depletion

## **Chapter 2: Lean NO<sub>x</sub> fuel penalty**

NO<sub>x</sub> chemistry

Selectivity

Activity

## **Chapter 3: Particulate filters fuel penalty**

Backpressure

Regeneration (Enthalpy)

# NO<sub>x</sub> Adsorber Fuel Penalties

## Assuming

Hydrogen to carbon ratio in the fuel	= 1.85 [mole/mole]
NO <sub>x</sub> Rate	= 2.5 [gm NO <sub>2</sub> /bHp/hr]
Air to Fuel Ratio	= 25:1 [lbm/lbm]
bsfc	= 0.350 [lb/bHp/hr]
lean:rich adsorption cycle	= 30:1 [sec/sec]

## Yields a fuel penalty of

adsorber NO <sub>x</sub> chemistry	= 0.405%
O <sub>2</sub> consumption using exhaust reductant	= 2.408%
<u>HC slip</u>	<u>= 0.088%</u>
total	= <b>2.9%</b>

# NO<sub>x</sub> Adsorber Chemistry

## Adsorption

overall

## Desorption with CO

## Reduction with CO

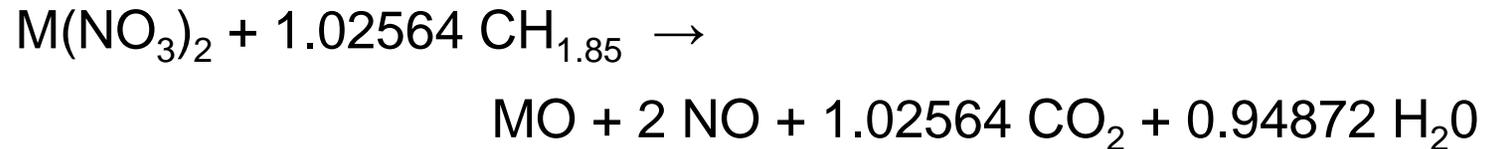

**∴ five moles of CO are required to desorb and reduce two moles of NO**

# NO<sub>x</sub> Adsorber Chemistry (cont.)

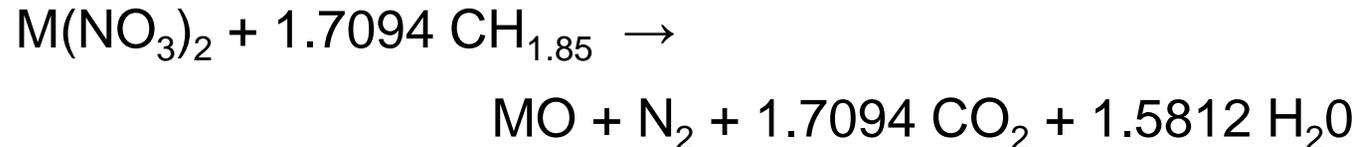

## Adsorption

## Desorption with CH<sub>1.85</sub>

## Desorption and reduction with CH<sub>1.85</sub>

**∴ 0.8547 moles of CH<sub>1.85</sub> are required to convert one mole of NO**

# NOx Chemistry Fuel Penalty

**NOX  $\equiv$  NO<sub>x</sub> reduction rate [gm NO<sub>2</sub>/bHp/hr]**

$$= \{ \text{NOX} / 46 \} [\text{mole NO}_2/\text{bHp/hr}]_{\text{environment}}$$

$$= \{ \text{NOX} / 46 \} [\text{mole NO}/\text{bHp/hr}]_{\text{engine exhaust}}$$

**stoichiometry**  $\rightarrow \{ \text{NOX} * 0.8547 / 46 \} [\text{mole CH}_{1.85} / \text{bHp/hr}]$

$$= \{ \text{NOX} * 13.85 * 0.8547 / 46 \} [\text{gm CH}_{1.85} / \text{bHp/hr}]$$

$$= \{ \text{NOX} * 13.85 * 0.8547 / 46 / 454 \} [\text{lb CH}_{1.85} / \text{bHp/hr}]$$

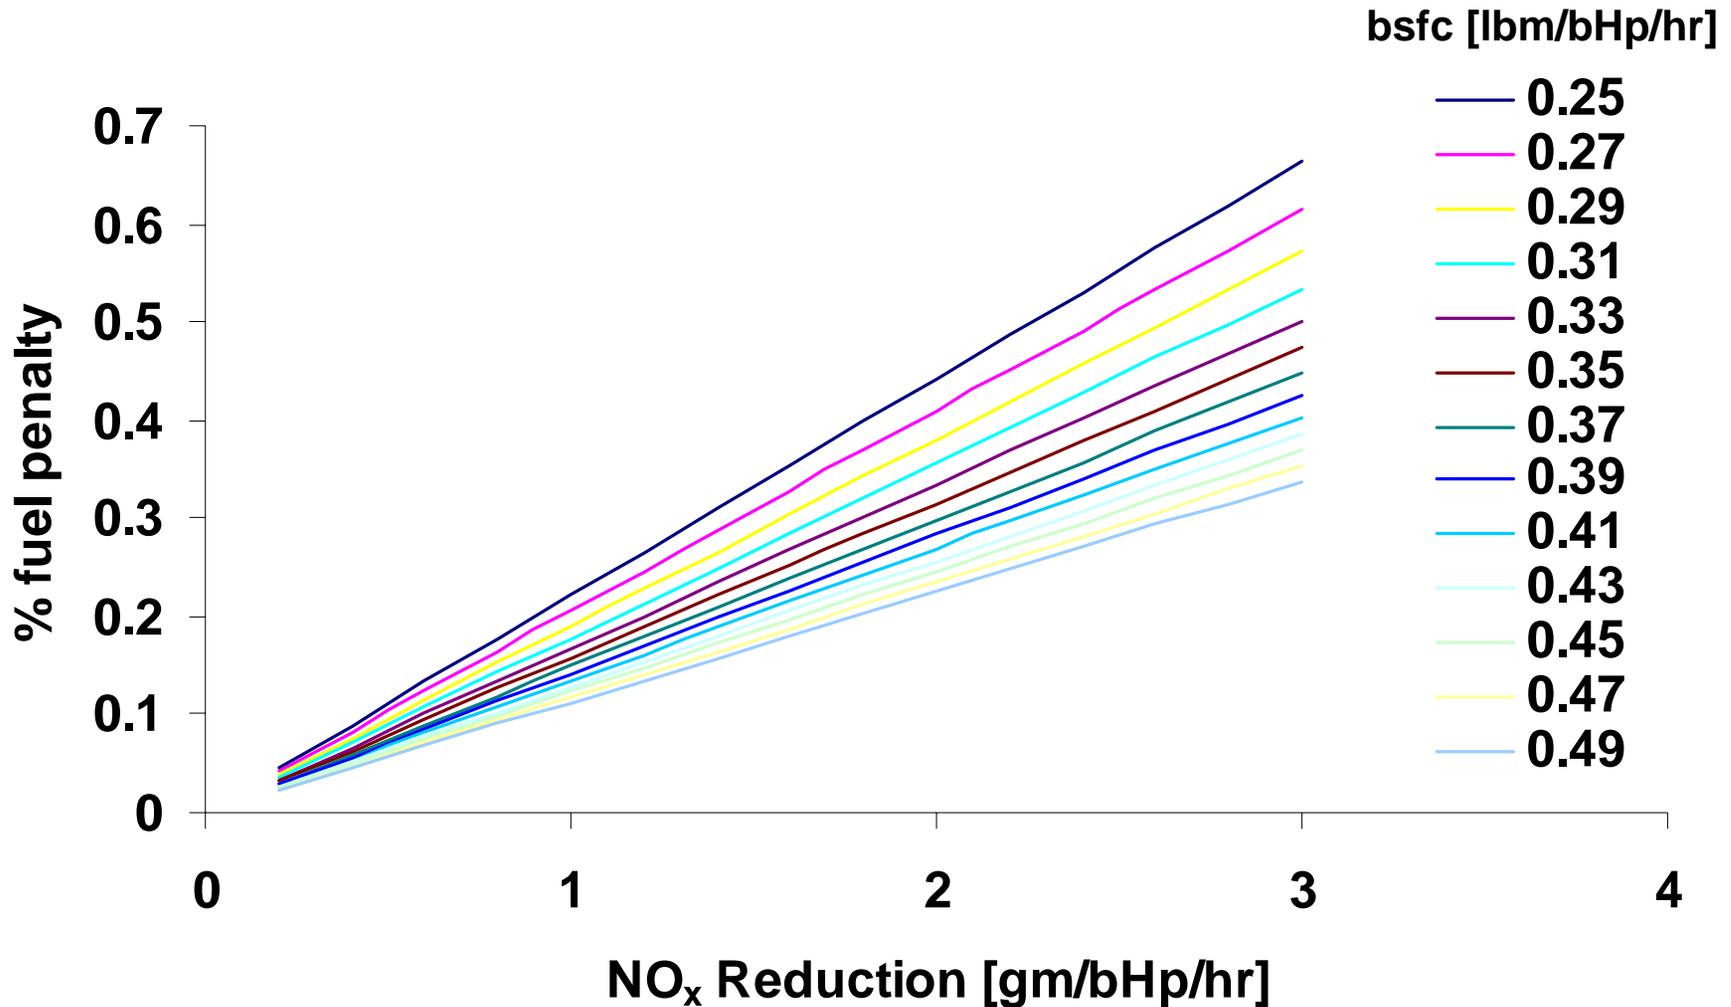

**$\therefore$  NO<sub>x</sub> chemistry fuel penalty (as a percentage):**

$$\{ 0.0567 * \text{NOX} / \text{BSFC} \} [\%]$$

**$\therefore$  Example:** To remove 2.5 gm of NO<sub>x</sub> at 0.350 bsfc:

$$0.0567 * 2.5 / 0.350 = \mathbf{0.405\%}$$

# NO<sub>x</sub> Chemistry Is Minor Factor

# HC Slip Fuel Penalty

**NMHC**  $\equiv$  **Non-Methane Hydrocarbon reduction rate**

$$\text{NMHC [gm CH}_{1.85}\text{/bHp/hr]} = \{\text{NMHC /454}\} [\text{lbm CH}_{1.85}\text{/bHp/hr}]$$

**HC slip fuel penalty (as a percentage) is simply the ratio:**

$$\{100 * \text{NMHC /454/ BSFC}\} [\%]$$

$\therefore$  **Example:** Assuming 2007HD NMHC level of 0.14g/bHp/hr and 0.350 bsfc:

$$\text{fuel penalty} = 100 * 0.14 / 454 / 0.350 = \mathbf{0.088\%}$$

**Note:** 0.088% assumes that no tailpipe HC are methane and that no stored (on the catalyst) HC are oxidized during the lean operating period

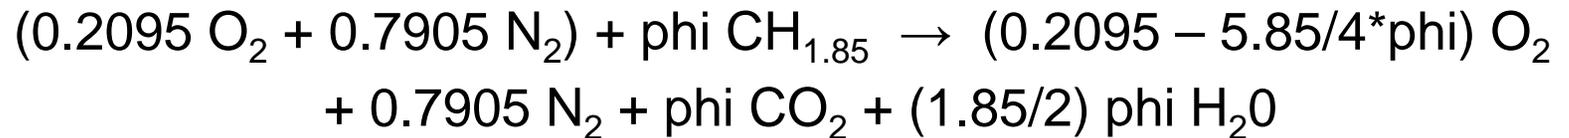

# Oxygen Consumption Fuel Penalty

## Stoichiometric Oxidation of $\text{CH}_{1.85}$

$\therefore$  stoichiometry = 0.68376 [mole  $\text{CH}_{1.85}$ /mole  $\text{O}_2$ ]

## Lean oxidation of $\text{CH}_{1.85}$

$\therefore$  exhaust oxygen concentration:

$$\{(0.2095 - 1.4625*\phi)/(1.0 + 0.4625*\phi)\} \text{ [mole O}_2 \text{ /mole exh]}$$

# O<sub>2</sub> Consumption Fuel Penalty (cont.)

**AFR**  $\equiv$  **Air to Fuel Ratio** [lbm air/lbm CH<sub>1.85</sub>]  
 $= \{28.96/\phi / 13.85\}$  [gm air/gm CH<sub>1.85</sub>]

**ExO<sub>2</sub>**  $\equiv$  **O<sub>2</sub> concentration in the exhaust** [mole O<sub>2</sub>/mole exh]  
 $= \{(0.2095 * \text{AFR} - 3.0581) / (\text{AFR} + 0.9670)\}$  [mole O<sub>2</sub>/mole exh]

Please note the following relationship for exhaust flow rate:

$$(\text{exhaust flow rate}) / (\text{fresh air flow rate}) = \{1.0 + 1.0/\text{AFR}\} [\text{lb} / \text{lb}]$$

# O<sub>2</sub> Consumption Fuel Penalty (cont.)

Putting it all together...

[mole CH<sub>1.85</sub> / mole exhaust] →

$$\{\text{ExO}_2 * 0.68376\}$$

[gm CH<sub>1.85</sub> / gm exhaust] →

$$\{\text{ExO}_2 * 0.68376 * 13.85 / 28.8\} \text{ see note}$$

[lbm CH<sub>1.85</sub> / lbm intake air] →

$$\{\text{ExO}_2 * 0.68376 * 13.85 / 28.8 * (1.0 +$$

1.0/AFR)\}

[lbm CH<sub>1.85</sub> / lbm engine fueling] →

$$\{\text{ExO}_2 * 0.68376 * 13.85 / 28.8 * (\text{AFR} + 1.0)\}$$

**Note:** exhaust gas molecular weight was assumed to be 28.8

# O<sub>2</sub> Consumption Fuel Penalty (cont.)

...yields the oxygen depletion fuel penalty:

$$[\text{lbm CH}_{1.85} / \text{lbm engine fueling}] \rightarrow \{(0.2095 * \text{AFR} - 3.058) / (\text{AFR} + 0.967) * 0.684 * 13.85 / 28.8 * (\text{AFR} + 1)\}$$

or approximately...

$$[\text{lbm CH}_{1.85} / \text{lbm engine fueling}] \rightarrow \{(0.2095 * \text{AFR} - 3.058) * 0.684 * 13.85 / 28.8\}$$

Finally, accounting for rich-lean cycling:

$$\{(6.89 * \text{AFR} - 100) / (\text{lean:rich})\} [\%]$$

∴ **Example:** To remove exhaust O<sub>2</sub> at 25 AFR and 30:1 lean rich yields a fuel penalty of:  $(6.89 * 25 - 100) / 30 = 2.41\%$

# Oxygen Consumption Fuel Penalty

## Three approaches:

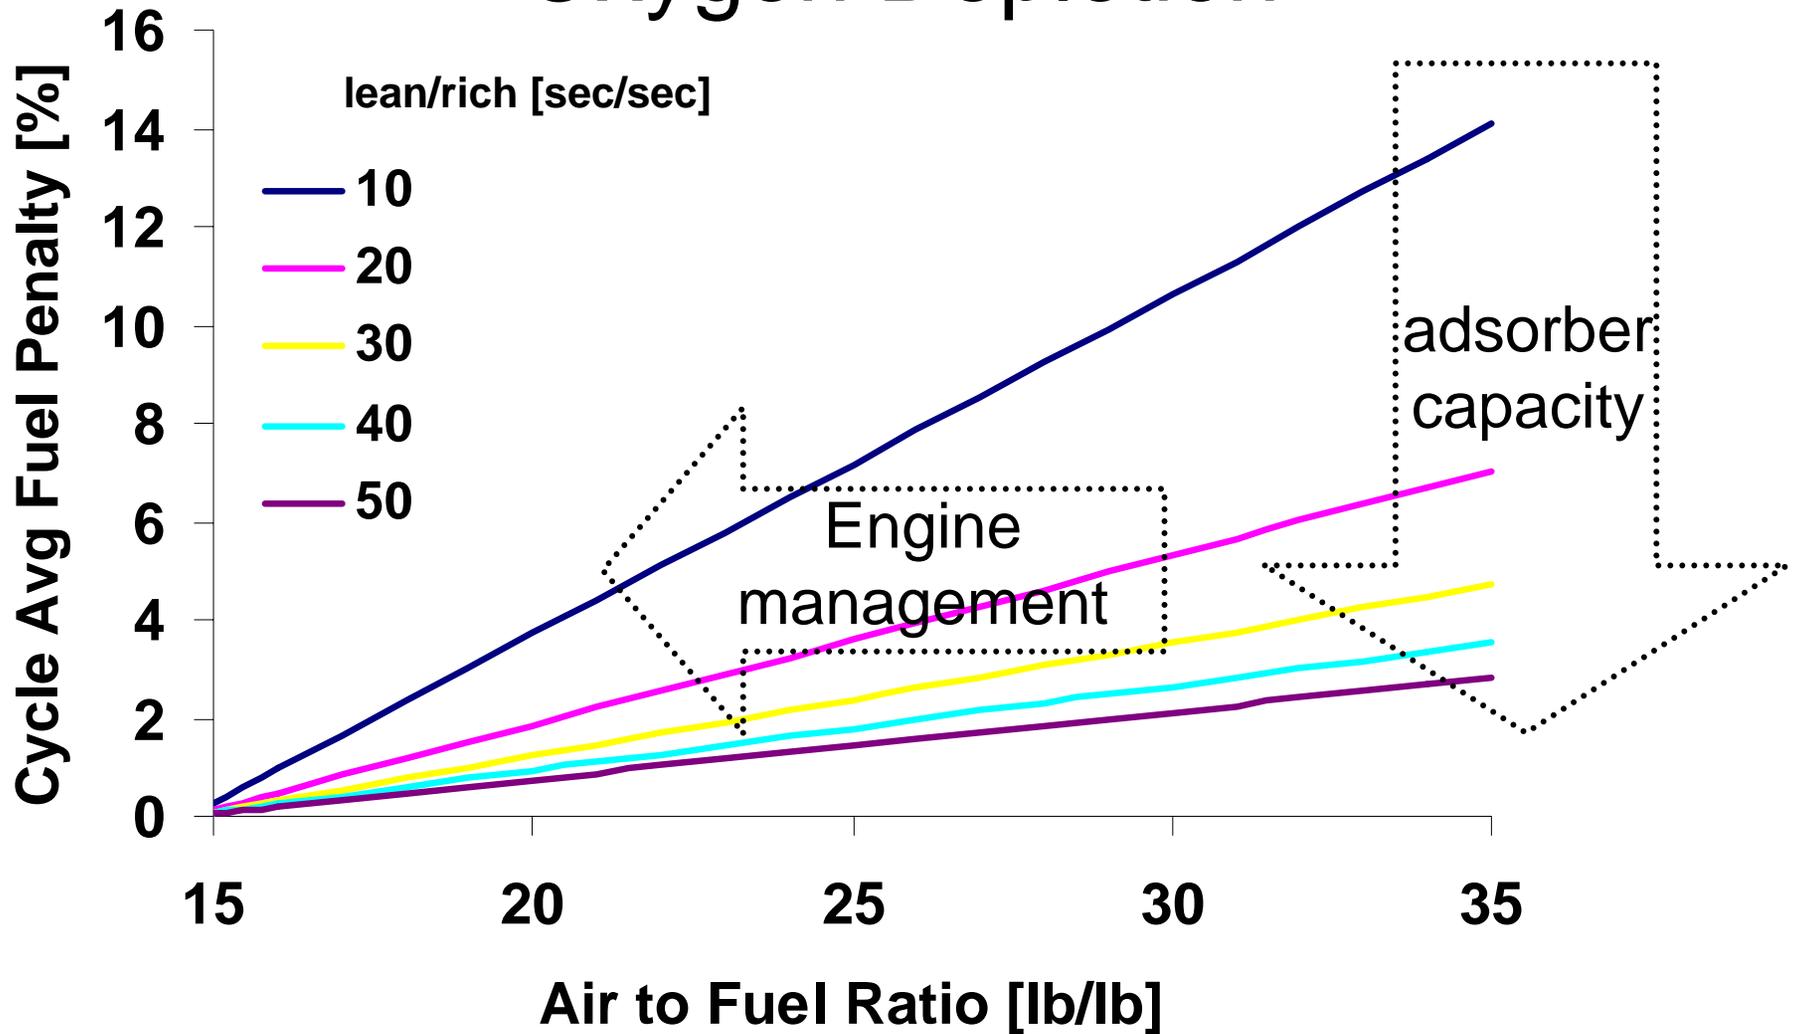

- reduce exhaust flow to the catalyst w/bypass
  - analysis done but not included (available on request)
- increase adsorption/regeneration time ratios
- operate the engine at low air/fuel ratios
  - throttle the engine (decrease air)
  - increase EGR rates (decrease air)
  - destroy efficiency (increase fuel)

# Oxygen Consumption Fuel Penalty

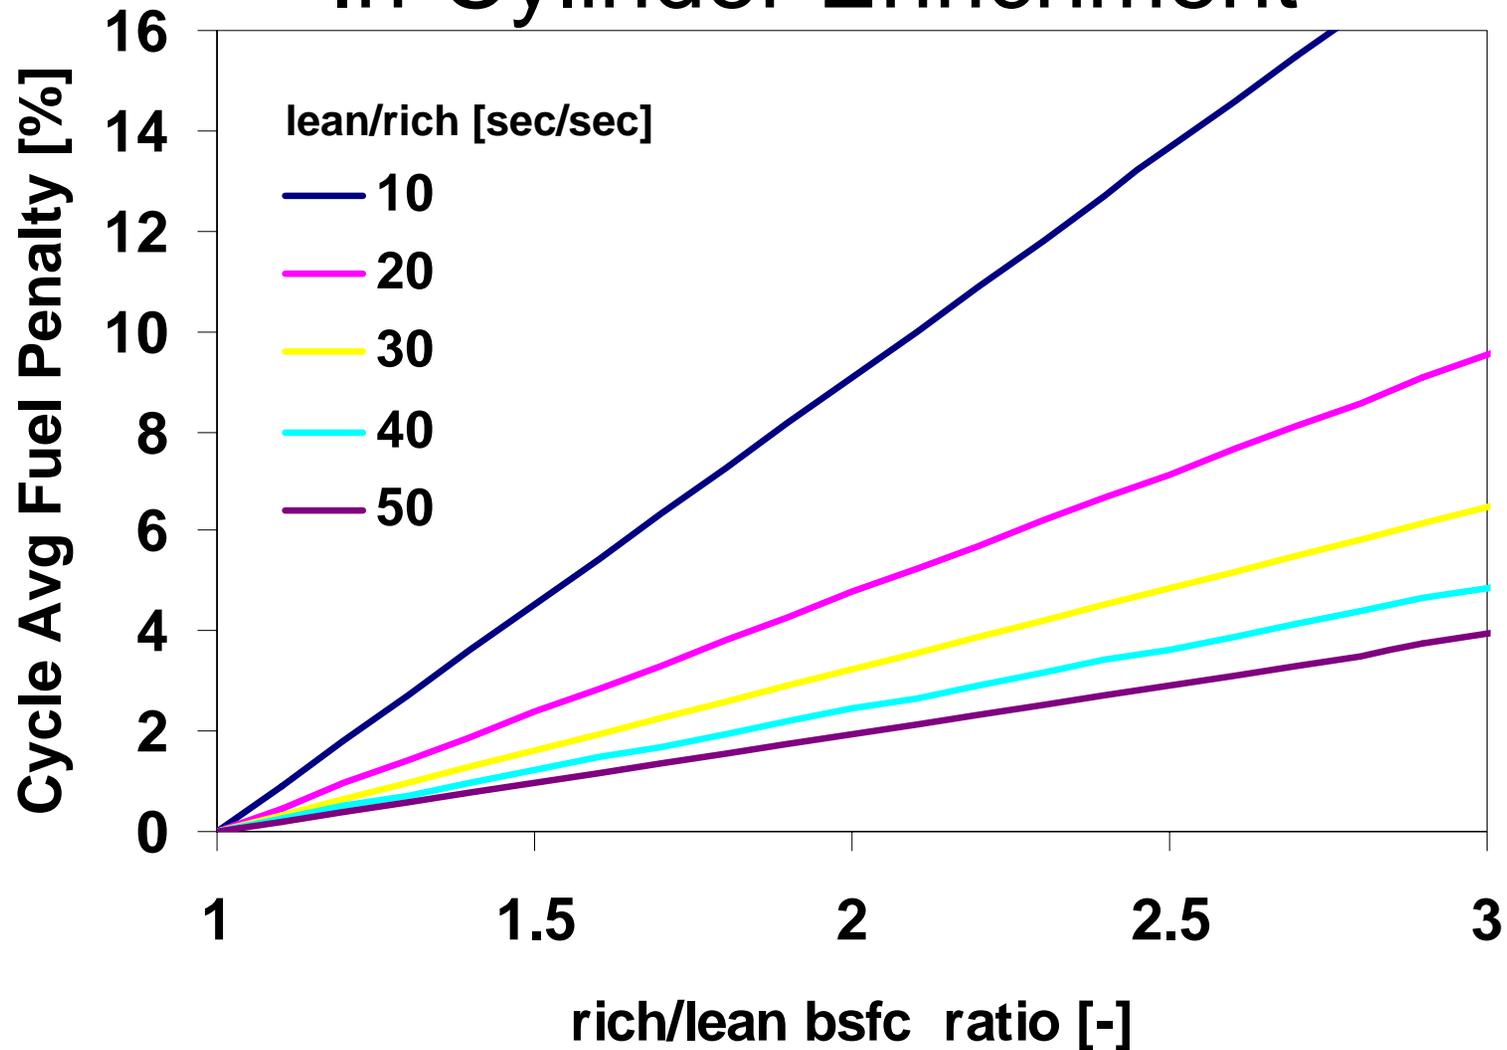

## Three approaches:

- ~~reduce exhaust flow to the catalyst w/bypass~~
  - ~~analysis done but not included (available on request)~~
- increase adsorption/regeneration time ratios
- operate the engine at low air/fuel ratios
  - ~~throttle the engine (decrease air)~~
  - increase EGR rates (decrease air)
  - ~~destroy efficiency (increase fuel)~~

# Oxygen Depletion

# In-Cylinder Enrichment

# Adsorber Fuel Penalty Equation

$$\begin{aligned}
 \text{penalty [\%]} = & \\
 & \{100*(0.000567)*\text{NOX} / \text{BSFC} \} + \\
 & \{100*\text{NMHC} / 454/ \text{BSFC} \} + \\
 & \{(0.206*\text{AFR} - 3.058)/(\text{AFR} + 0.967) * \\
 & \quad 0.684*13.85/28.8*(\text{AFR} + 1.0) / \\
 & \quad (\text{lean:rich})\}
 \end{aligned}$$

# Conclusion #1

**With maturity NO<sub>x</sub> Adsorbers will allow engine retune**

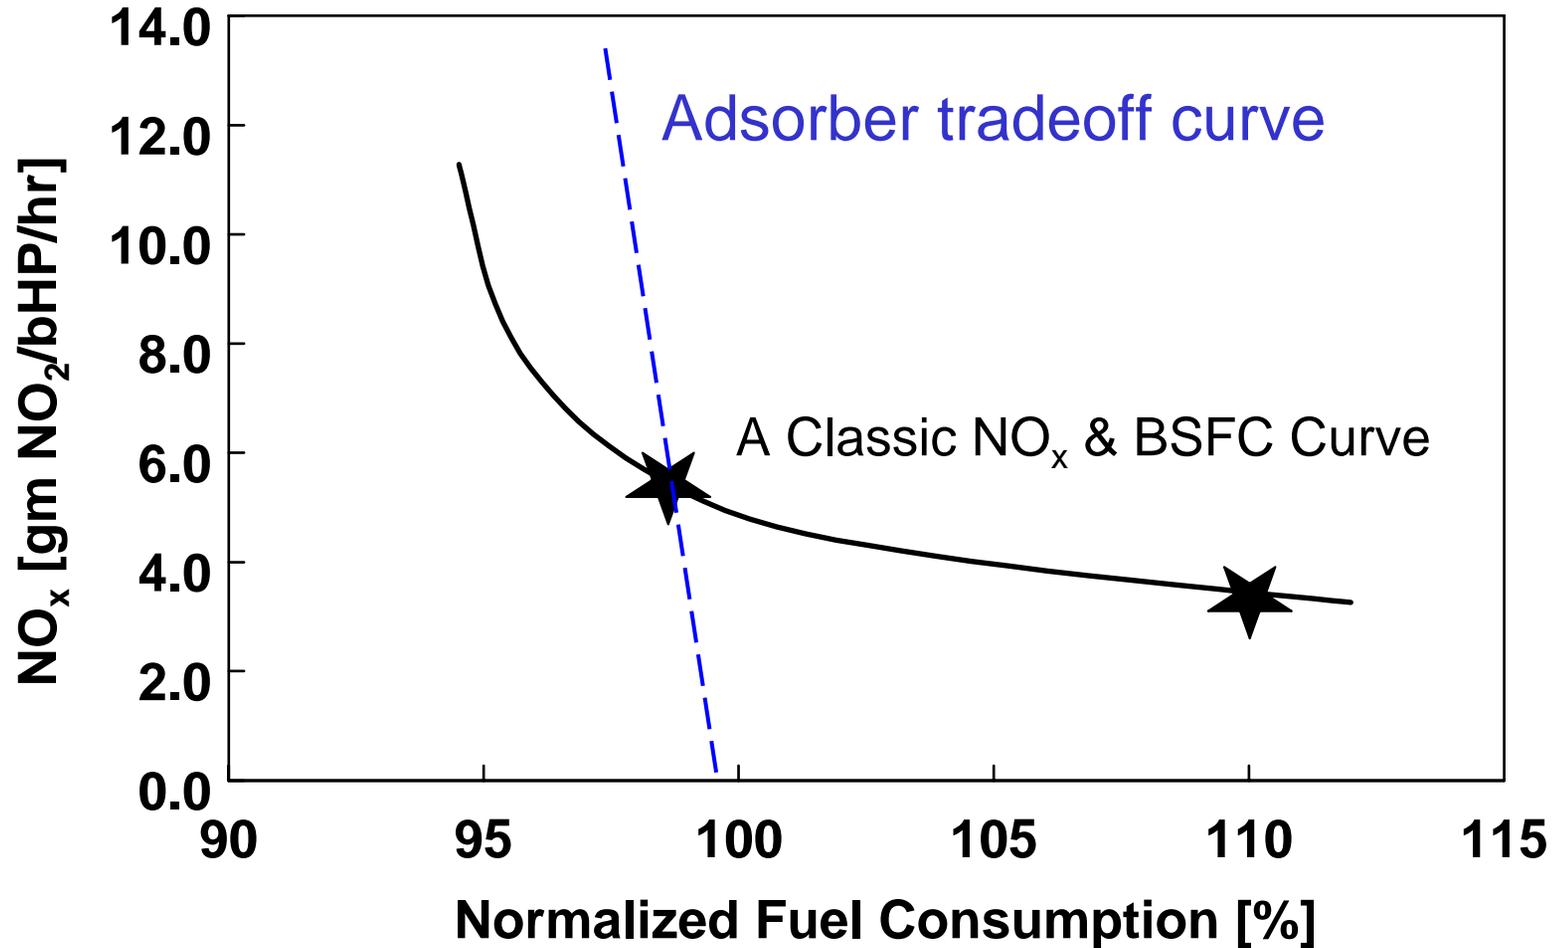

2.5 gm NO<sub>x</sub> → 2.9% fuel penalty

5.0 gm NO<sub>x</sub> → 3.3% fuel penalty

**Note:** this argument is not unlike the case some are making for urea-SCR (primarily in Europe)

**Key science need – better understanding of the desorption/regeneration phenomenon**

# Aftertreatment will save fuel!

## Conclusion #2

**Given that O<sub>2</sub> depletion is the biggest piece of the fuel penalty and the strong relationship with Air-to-Fuel ratio,**

$$\{(6.89 \cdot \text{AFR} - 100) / (\text{lean:rich})\} [\%]$$

**NO<sub>x</sub> Adsorbers will have a relatively larger fuel penalty under lighter load operating conditions.**

2.4% penalty at 25:1 AFR

10.5% penalty at 60:1 AFR

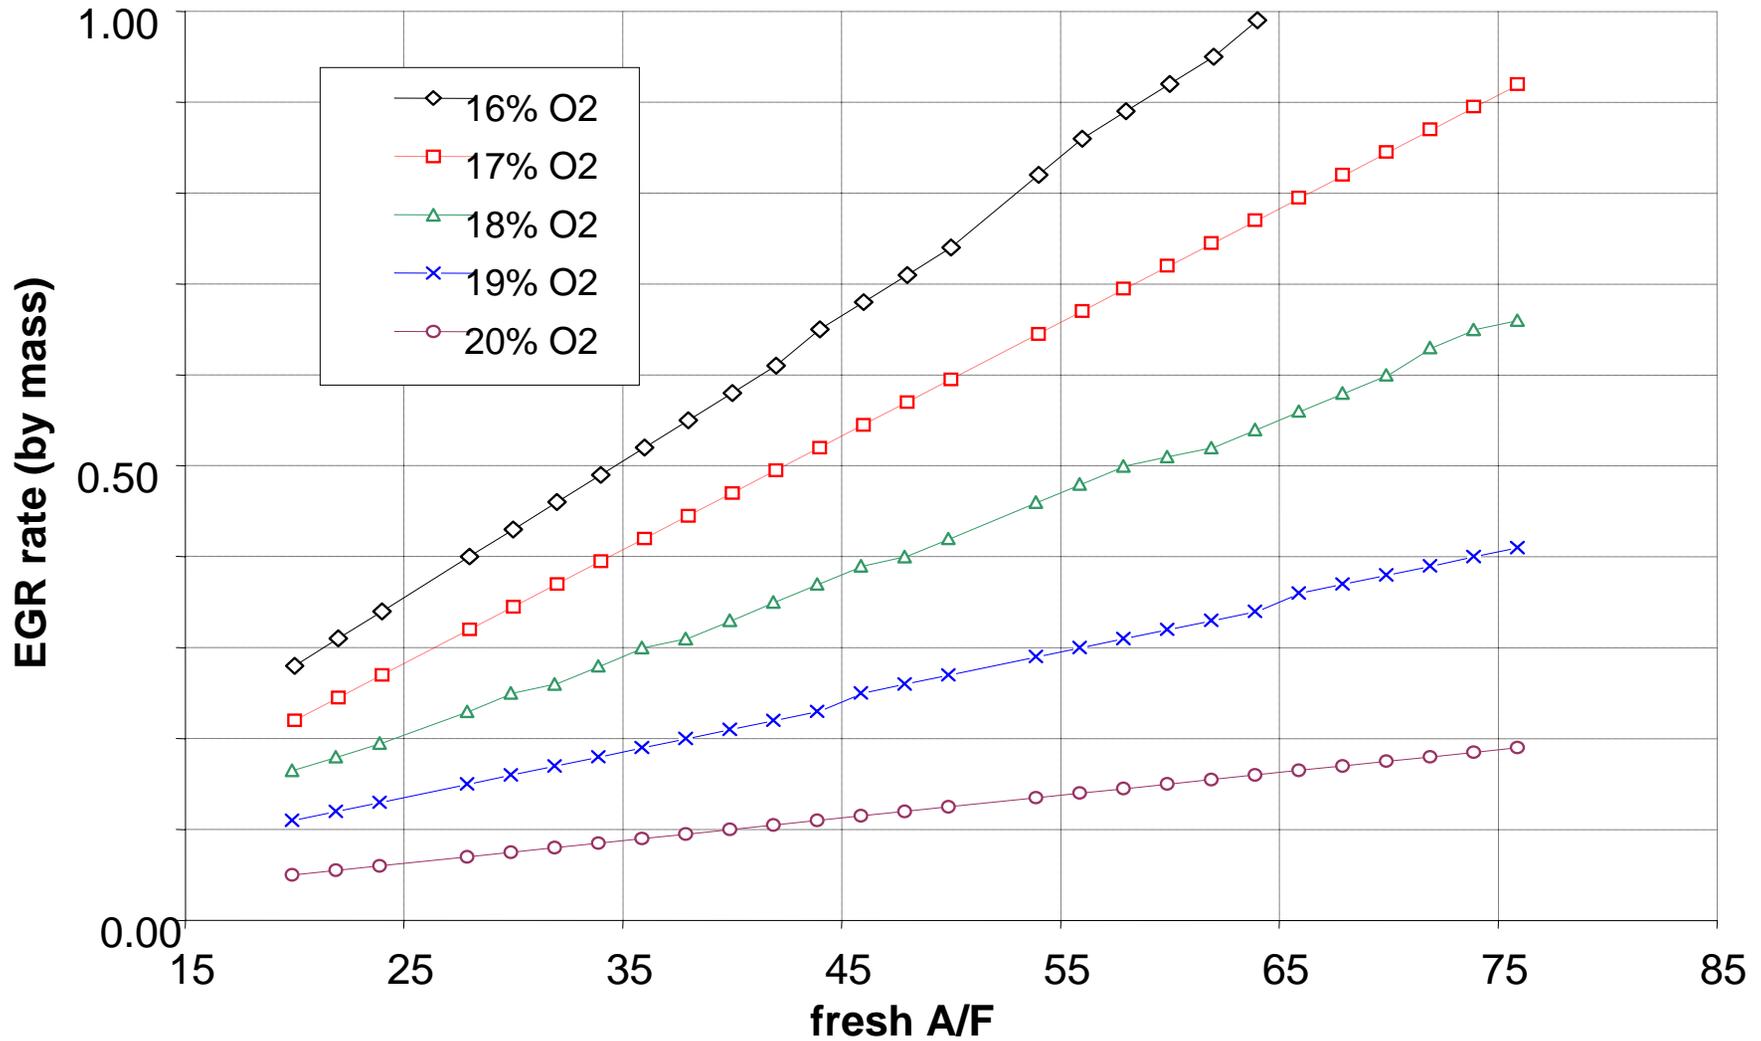

20% penalty at 100:1 AFR

**Which implies one of two strategies:**

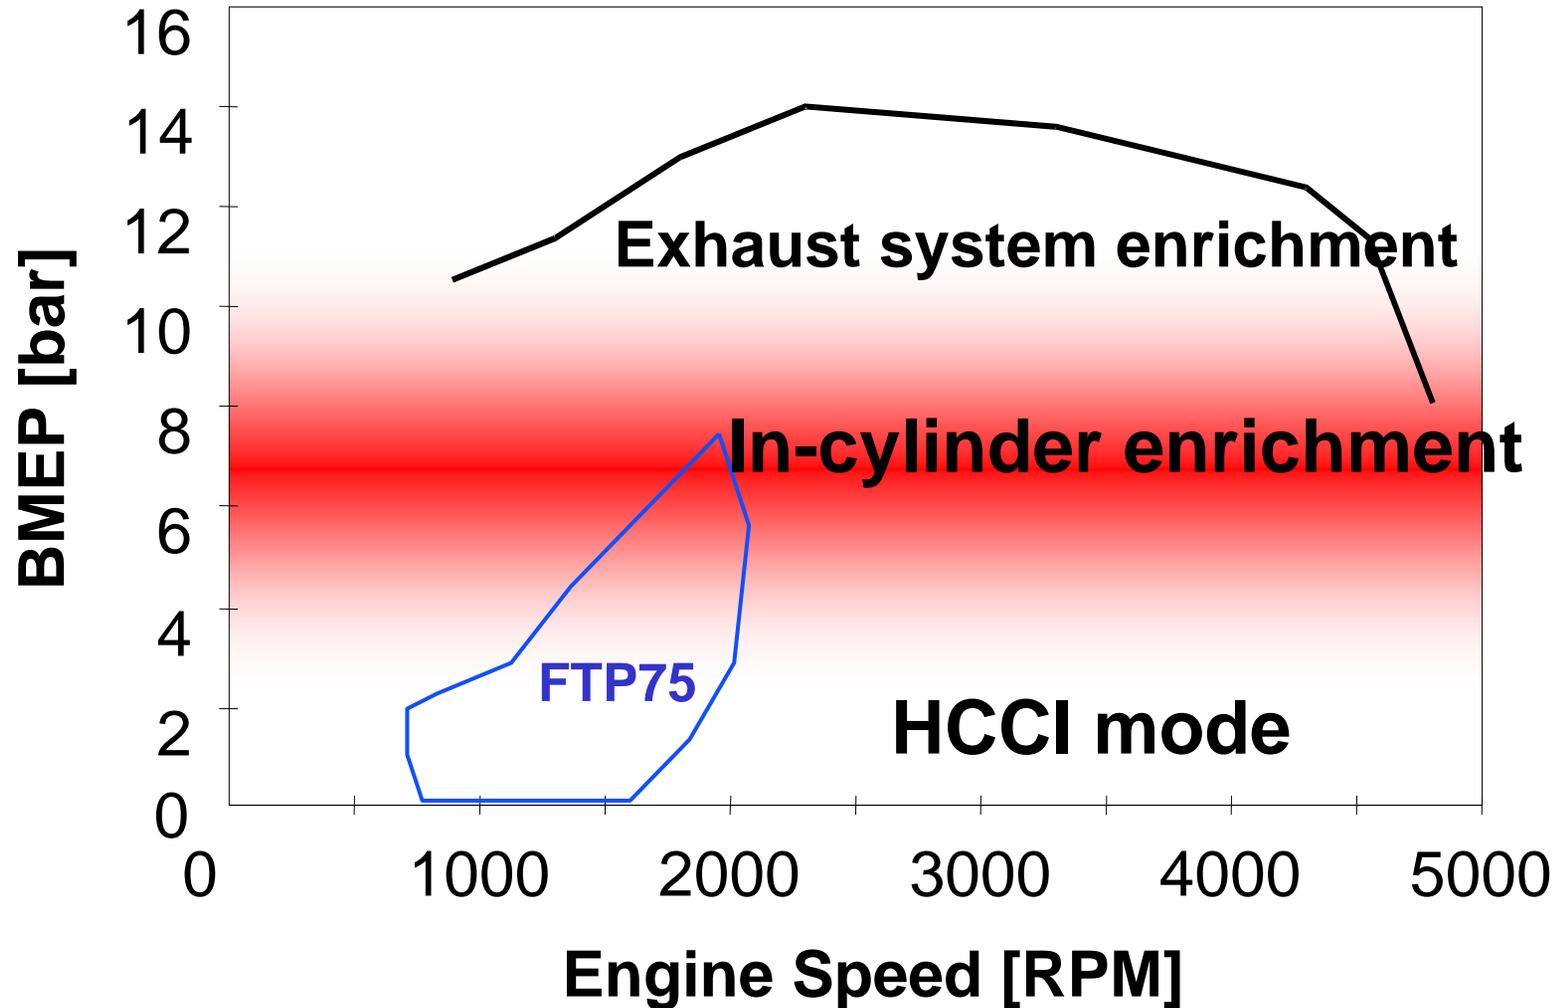

(massive) EGR rates for AFR reduction

dual mode w/HCCI-like combustion at light loads

# EGR Effect on Oxygen Concentration

# HCCI(like) Combustion and NOx Adsorbers

Activity

## **Particulate Filters**

Backpressure

Regeneration (Enthalpy)

# HC Lean NO<sub>x</sub> Fuel Penalties

## Assuming

Hydrogen to carbon ratio in the fuel	= 1.85 [mole/mole]
NO <sub>x</sub> Rate	= 2.5 [gm NO <sub>2</sub> /bHp/hr]
Air to Fuel Ratio	= 25:1 [lbm/lbm]
bsfc	= 0.350 [lbm/bHp/hr]
C:N (typical optimum for lean NO <sub>x</sub> )	= 6 [m CH <sub>1.85</sub> /m NO]

## Yields fuel penalties of

Ideal lean NO <sub>x</sub> chemistry	= 0.162%
Actual lean NO <sub>x</sub> chemistry	= 2.84%
Current system selectivity	= 2.85%

**Note:** Higher C:N yields better reduction but with diminishing returns

# Ideal Lean NO<sub>x</sub> Chemistry

## Ideal NO<sub>x</sub> reduction with CH<sub>1.85</sub>

∴ 0.3419 moles of CH<sub>1.85</sub> are required to convert one mole of NO

## From ideal lean NO<sub>x</sub> chemistry

$$= \text{NOX} [\text{gm NO}_2/\text{bHp/hr}]$$

$$\text{stoichiometry} \rightarrow \{\text{NOX} * 0.3419/46\} [\text{mole CH}_{1.85}/\text{bHp/hr}]$$

$$= \{\text{NOX} * 13.85 * 0.3419/46/454\} [\text{lb CH}_{1.85}/\text{bHp/hr}]$$

∴ **Ideal fuel penalty (as a percentage):**

$$\{100 * 13.85 * 0.3419/46/454 * \text{NOX} / \text{BSFC}\} [\%]$$

∴ **Example:** To remove 2.5 gm of NO<sub>x</sub> at 0.350 bsfc:

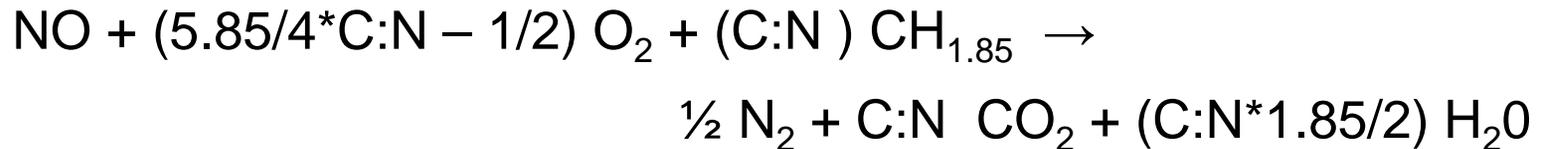

$$100 * 0.000227 * 2.5/0.350 = \mathbf{0.162\%}$$

# Real Lean NO<sub>x</sub> Chemistry

**C:N**  $\equiv$  carbon to NO<sub>x</sub> molar ratio - unit conversion

$$\text{C:N} [\text{moles CH}_{1.85}/\text{moles NO}] \rightarrow \{\text{C:N} * 13.85/46\} [\text{gm HC/gm NO}_2]$$

**SELECTIVITY: lean NO<sub>x</sub> reduction competes with direct oxidation**

$$\therefore \text{Selectivity} = \{100 * 0.3419 / \text{C:N}\} [\%]$$

$\therefore$  **Fuel penalty (as a percentage):**

$$\{100 * 13.85/46/454 * \text{C:N} * \text{NOX} / \text{BSFC}\}$$

[%]

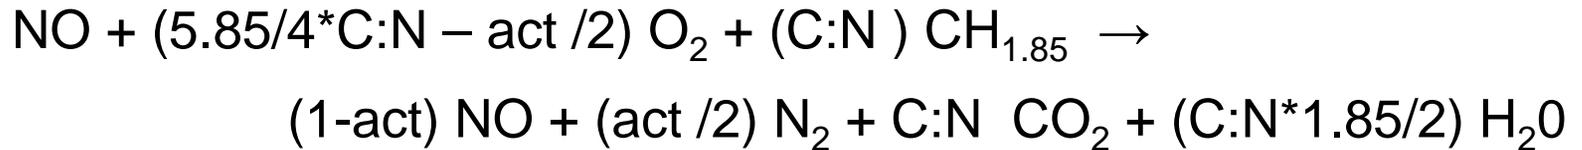

$\therefore$  **Example:** To remove 2.5 gm of NO<sub>x</sub> at 0.350 bsfc with a C:N of 6:

$$0.06632 * 6 * 2.5 / 0.350 = \mathbf{2.84\%}$$

$$(\text{w/selectivity of: } 100 * 0.3419 / 6 = \mathbf{5.70\%})$$

# Real Lean NO<sub>x</sub> Chemistry (cont.)

**ACTIVITY: lean NO<sub>x</sub> reduction is not yet 100% efficient**

∴ **Activity impacts selectivity.**

$$\text{Selectivity} = \{100 * \text{act} * 0.3419 / \text{C:N}\} [\%]$$

∴ **Example:** To remove NO<sub>x</sub> at 50% efficiency with a C:N of 6 yields a selectivity of  $\{100 * 0.5 * 0.3419 / 6\} = \mathbf{2.85\%}$

**Note:** I'm being somewhat loose with my definition of selectivity and activity.

# Conclusion

**Lean NO<sub>x</sub> catalysis is the 'Holy Grail' for diesel engines**

**minimal complexity**

**low impact on engine design**

**potentially low cost**

**potential for high durability and reliability**

**Like absorbers, if lean NO<sub>x</sub> catalysis can be made to work they  
WILL ultimately prove to be a fuel SAVINGS device.**

**However!**

**Key science - We need (HC) lean NO<sub>x</sub> to be (*nearly*) as  
selective and active as urea-SCR.**

# Overview

## **NO<sub>x</sub> Adsorbers**

NO<sub>x</sub> chemistry

HC slip

Oxygen depletion

## **Lean NO<sub>x</sub>**

NO<sub>x</sub> chemistry

Selectivity

Activity

## **Particulate Filters**

Backpressure

Regeneration (Enthalpy)

# Particulate Filter Fuel Penalties

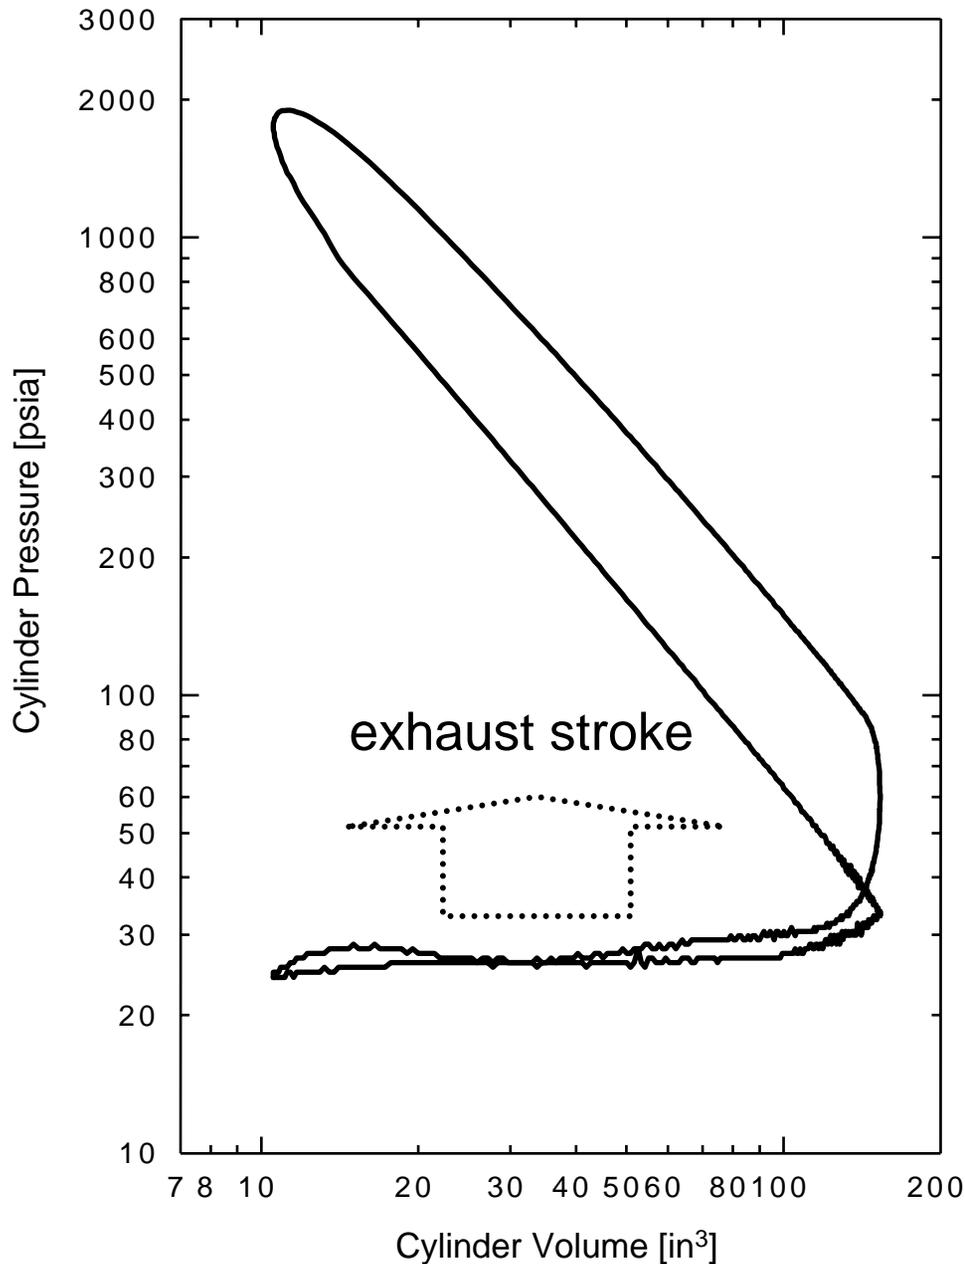

## Assuming

BMEP	= 100 [psi]
Backpressure	= 1 [psi]
Air to Fuel Ratio	= 25:1 [lbm/lbm]
bsfc	= 0.350 [lbm/bHp/hr]
Temp rise in exhaust (dT)	= 100 [deg F]
Regeneration duty cycle (DC)	= 10%

## Yields fuel penalties of

Backpressure fuel penalty	= 1.0%
<u>Cycle average regeneration penalty</u>	<u>= 0.34%</u>
Total penalty	= <b>1.34%</b>

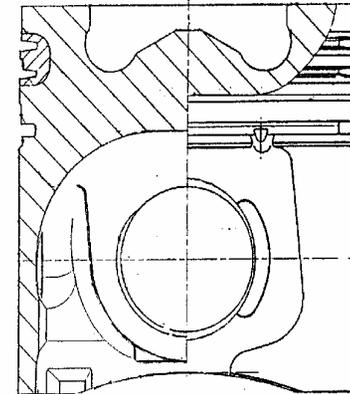

**Note:** These penalties are highly duty-cycle dependent!

# Backpressure

BMEP is directly impacted by backpressure

**pressure = work**

# Backpressure

## Assuming

BMEP = 100 [psi]

Backpressure = 1 [psi]

## From simple reasoning

one psi backpressure removes one psi of useful work from the piston which must be recovered from increased fueling:

approx. fuel penalty =  $\{100 \cdot \text{backpressure} / \text{bmep}\}$  [%]

∴ **Example:** One psi backpressure at 100 psi bmep:  
 $\{100 \cdot 1.0 / 100\} = \mathbf{1.0\%}$

# Enthalpy

## Assuming

Diesel fuel heating value (higher)	= 18500 [Btu/lbm]
$C_p$	= 0.2412 [Btu/lbm/F]
Duty Cycle (DC)	= 10 [%]

## From $dH = C_p dT$

$$18500 \text{ [Btu/lbm suppl. fuel]} = 0.2412 \text{ [Btu/lbm exhaust/deg F]} * \\ dT \text{ [deg F]} * (AFR + 1) \text{ [lbm exh/lbm fueling]} * \\ (1/\text{efficiency}) \text{ [lbm fueling/lbm suppl. Fuel]}$$

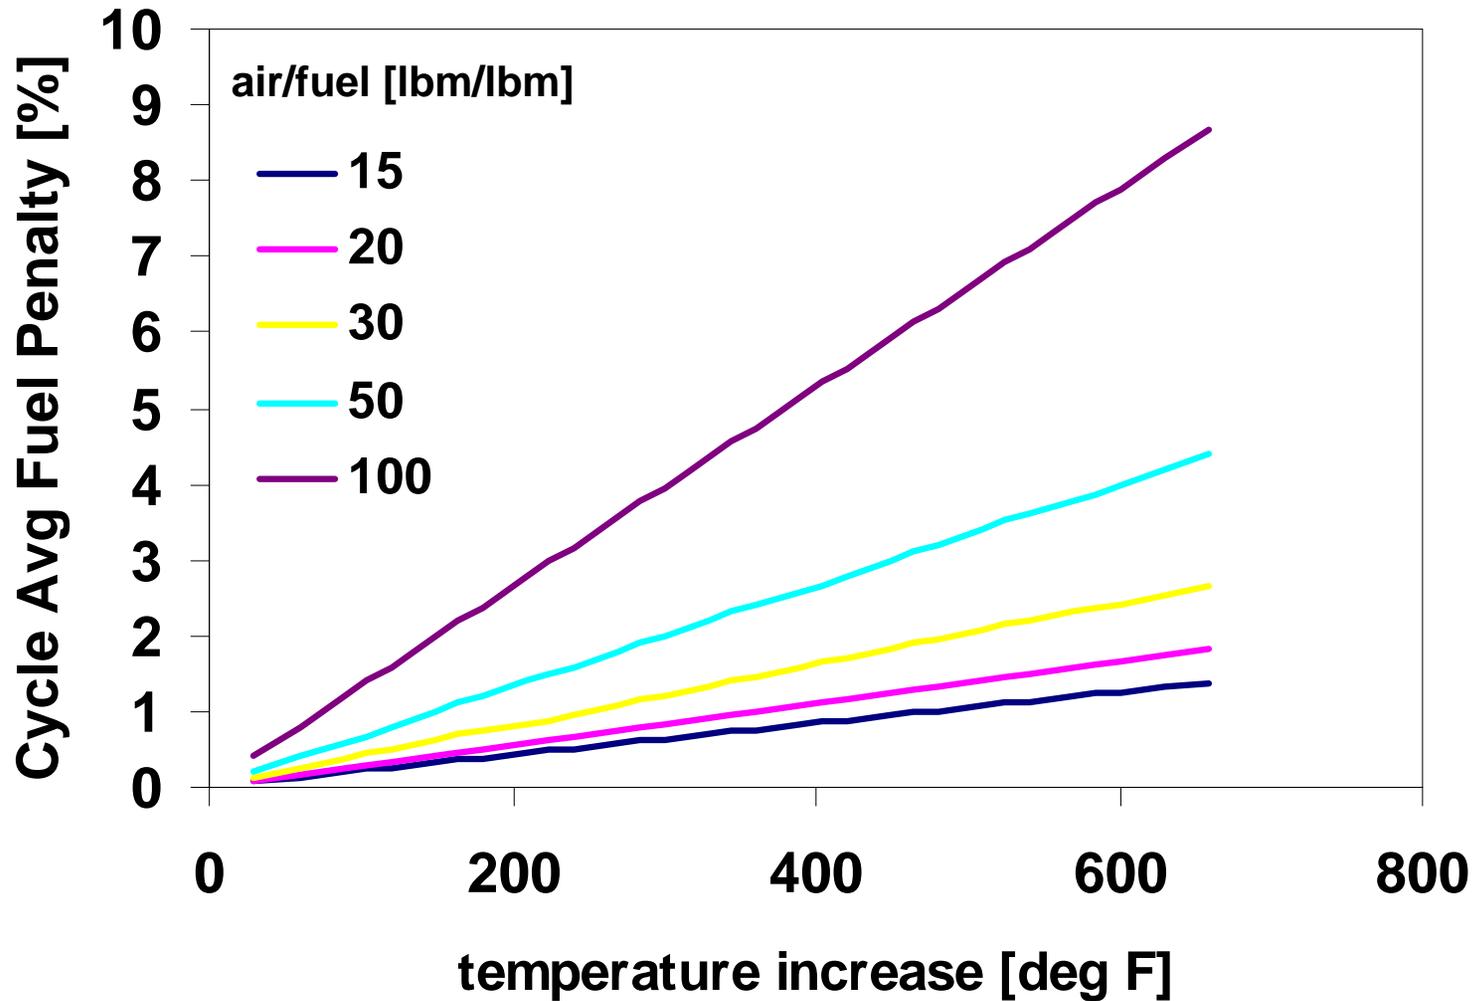

∴ **fuel penalty during regen is...**

$$\{(1+AFR)*0.2412*dT/18500*DC\} \text{ [%]}$$

∴ **Example:** Penalty for 100deg F rise at 25 AFR:

$$(1+25)*0.2412*100/18500*10 = \mathbf{0.34\%}$$

# DPF penalty w/10% duty cycle

# Conclusion

**DPFs are unlikely to ever enhance a total system efficiency.  
Engine retune for efficiency will likely reduce DPF burden.  
Best one can hope for is to minimize the penalty.**

## **Soot filter penalties are difficult to estimate**

- # active regens required is entirely duty-cycle dependant
- backpressure is linked to regen history and flowrates
- soot oxidation characteristics are poorly understood

**Key science – soot oxidation characterization, prediction and enhancement.**

Once it has “emerged”...

**...NO<sub>x</sub> aftertreatment has the potential to improve diesel engine fuel economy over current state-of-the-art**

And if you don't believe it...

**...consider where we have come in the last  
25 years with TWC on gasoline engines!**

**Would you have believed that 30 years ago?**
