From Tragedy to Triumph—Rebuilding with Renewable Energy after Disaster

Renewable energy is generated from sources that are “green” and naturally replenished such as sunlight, wind, and geothermal heat. This energy can power, heat, and cool buildings, and can replace traditional sources of fuel (e.g., coal and natural gas) used by utilities. Most utilities are using wind power, but other types are coming to the forefront. Every day, more individuals, businesses, and communities decide to “go green” with renewable energy.

Renewable Energy Benefits

• Generates electricity from the sun or wind
• Heats and cools quietly and naturally
• Grants tax credits to building owners
• Offers protection against rising utility bills
• Supplies reliable power after natural disasters
• Protects the environment.

Energy Efficiency First

Lower energy demand means renewable energy systems can be smaller and less expensive. Consider these basic energy efficiency strategies:

• Use efficient insulation for foundations, walls, and roofs
• Look for ENERGY STAR® doors and windows and double-paned windows with “low-e” glazing
• Seal openings and cracks to reduce cooling and heating costs

Types of Renewable Energy

Solar

Solar power technologies take advantage of a large, clean, free renewable energy source—the sun. Solar technologies are scalable—they’re suitable for very small to very large applications. There are several types of solar technologies:

Solar photovoltaics (PV) convert sunlight directly to electricity and can be installed on individual rooftops or as large “fields” of solar arrays by a utility company.

Concentrating solar power (CSP) systems concentrate the sun’s heat to drive a generator that produces electricity. Most CSP systems are installed by utility companies and may consist of a field of dishes, engines, parabolic troughs, or central power towers.

Solar heating technologies use collectors that absorb the sun’s heat for water or space heating.

Solar lighting technologies include “clerestory” windows, skylights, and solar tubes that bring sunlight into a building where light is most needed.

Passive solar heating and daylighting strategies are integrated into designs so buildings work with the sun to operate more efficiently.

Rebuilding a community, a business, or a home after a natural disaster such as a flood, hurricane, or tornado can be daunting. Tragedy can be turned into opportunity by rebuilding with renewable energy and creating healthier and more energy-efficient communities.
Rebuilding Green in Greensburg

After a tornado devastated their town in May 2007, the citizens of Greensburg, Kansas, turned disaster into opportunity by rebuilding as a model “green” community. Their master plan includes goals for making residential and commercial buildings more energy efficient and developing community- and small-scale renewable energy projects.

Community-Scale Renewable Energy Projects

The City of Greensburg, which doubles as a municipal utility, is developing large-scale renewable energy resources. One project is the Greensburg Wind Farm, a joint effort of the City of Greensburg, the Kansas Power Pool, and John Deere Renewable Energy, that will consist of ten 1.25-MW wind turbines. The wind farm is expected to be operational in 2010 and will generate enough energy to power every home, business, and municipal facility in Greensburg. Excess electricity will be sold back to the local utility.

Financing for the project was supported by Native Energy Inc., which will be the exclusive marketer of Renewable Energy Certificates (RECs) from the wind farm. RECs, also called green tags, green certificates, or tradable renewable certificates, capture the environmental attributes—typically in terms of avoided emissions—of the power produced from renewable energy. They are sold separately from the electricity that runs through the grid. Usually, 1 REC represents proof that 1 megawatt-hour of electricity has been generated from an eligible renewable energy resource. Native Energy will purchase about two-thirds of the wind farm’s expected RECs over 20 years.

The city is also working with surrounding counties to explore options for using agricultural wastes to produce energy.

Small-Scale Renewable Energy Projects

Greensburg completed a study outlining the opportunities for solar PV to generate electricity on individual homes and businesses. The city also has adopted an interconnection agreement and net-metering policy that will give home and business owners credit from the local utility for excess power produced by their systems. In such distributed systems, buildings both receive and send electricity to the grid through an interconnection agreement.
And net-metering policies allow the owner of a distributed system to get the most value for the electricity sent back to the grid.

Wind
In certain areas, the wind is another resource for producing renewable energy. Wind turbines convert the wind’s kinetic energy into mechanical power, which is sent to a generator that converts the mechanical power into electricity. Wind energy can also be used for specific needs such as pumping water.

Single small turbines, rated in the 5–50 kilowatt (kW) range, can power homes, ranches, or remote buildings (zoning restrictions may apply, so check with your local zoning authority).

Turbines in the 5–100-kW range may benefit commercial buildings in appropriate locations.

Utility-scale turbines from 100 kW to several megawatts (MW) are grouped together into wind farms, often 100 MW or more in total capacity, which supply power to the electrical grid in bulk.

Geothermal
Geothermal energy is heat that resides deep within the rock and fluid of the earth’s crust. This energy can be harnessed to produce electricity or direct heat, or for heating and cooling buildings.

Electrical power plants use steam from geothermal reservoirs to rotate turbines that activate generators for producing electricity.

Small-scale geothermal power plants—under 5 MW—have the potential for widespread community application where geothermal resources are abundant, possibly as “distributed energy” resources (a variety of small, modular, power-generating technologies that can be combined to improve the operation of the electrical grid).

Ground-source heat pumps typically comprise a ground heat exchanger (a system of pipes called a loop, which is buried in the shallow ground near the building), a heat pump unit, and a series of ducts through which air is delivered. A fluid—usually water or a mixture of antifreeze and water—circulates through the pipes to absorb or relinquish heat. In the winter, the heat pump removes heat from the exchanger and pumps it through the ducts. The process is reversed in the summer, when the pump moves heat from the indoor air into the heat exchanger.

Biomass
When most people think of using biomass, ethanol from corn and biodiesel from soybean oil spring to mind. Other types of biomass have the potential to contribute to our energy mix as well. Dedicated energy crops such as fast-growing trees and grasses can be grown sustainably on land that is unsuitable for food crops. Forestry or agricultural residues, such as wheat straw and the stalks, leaves, and husks of the corn plant, called “stover,” are all biomass. Even the organic components of municipal and industrial wastes are usable for energy production.

Biomass is used to make liquid fuels for transportation, as in the cases of ethanol and biodiesel.

Most of us are familiar with consuming biomass to generate heat. Firewood and other biomass such as corn cobs can be burned to heat buildings. Biomass can also be “pelletized” to burn more cleanly and efficiently than firewood in heating stoves.

Utilities and major industries consume biomass directly or convert it to a gaseous fuel to generate electricity. Many coal-fired power plants today add biomass to their coal-burning process. This practice, called co-firing, reduces emissions while producing electricity. And industries such as pulp and paper and forest products often use biomass to co-generate heat and electricity.
Some of these uses for biomass have been commercialized for a long time; other uses are in development and are not yet commercial. For example, the first pilot-scale ethanol plants that use biomass other than corn are just being constructed.

Financing Renewable Energy

Financial Incentives

Numerous financial incentives, such as federal and state tax credits and utility rebates, are available to help offset the cost of a renewable energy system. Many utility companies also offer net metering for grid-connected renewable energy systems, so consumers can get credit for power they produce but don’t need. And the American Recovery and Reinvestment Act, signed into law on February 17, 2009, contains provisions that will financially benefit individuals, businesses, organizations, and the renewable energy industry as a whole.

For more information about financial incentives, visit the Database of State Incentives for Renewables and Efficiency at www.dsireusa.org.

Power Purchase Agreements

A power purchase agreement (PPA) is a financing mechanism created to help businesses, industrial concerns, schools and universities, and all levels of government go green with no up-front capital cost. Through these long-term contracts (about 15 years or more) a renewable energy company (PPA partner) finances, owns, and maintains the renewable energy system. The buyer agrees to purchase the electricity generated by the system from the PPA partner, which has assumed all the risks and responsibilities of ownership. At the end of the PPA term, the buyer can choose to purchase the system or extend the agreement. A PPA with predetermined electricity rates over the term of the contract helps to stabilize operating costs that were once highly variable.
